Introduction: Electric field distributions along a polymeric insulator under wet and contaminated conditions were studied in this paper. Pollution layer was modelled as a conductive water layer and conductivity was varied from 10-6 to 10-3 S/m. Similarly, thickness of pollution layer was varied from 0.5 to 2 mm in steps of 0.5.

Results: Electric field intensity along the insulator surface was greatly influenced by pollution layer thickness and conductivity. As the pollution layer thickness was changed from 0.5 to 2 mm, the electric field increase from 1.12 to 1.65 kV/cm. In the case of pollution layer conductivity highest electric field stress was calculated for layer conductivity of 10-3 S/m. Pollution layer thickness was kept constant at 1 mm in this case.

Computational Methods: Electric currents formulation was used to study the effect of pollution conductivity on the electric field distribution. The equation governing the electric field computation is Comsol is given below [10].

\[ \nabla \cdot J = Q_j \]

\[ J = (\sigma + j\omega \varepsilon_o \varepsilon_r + J_e) \]

\[ \nabla E = \frac{\rho}{\varepsilon} \]

\[ \varepsilon \nabla (\nabla E) = 0 \]

Conclusions: Based on the simulation results it was concluded that electric field is greatly influenced by pollution layer conductivity and thickness. As the pollution layer conductivity and thickness increases, electric field intensity increases. The highest electric field was observed to be 1.65 kV/cm in the case of a 2-mm thick pollution layer.
